DOCUMENT-IDENTIFIER: US 5974238 A

TITLE: Automatic data synchronization between a handheld and a host computer using pseudo cache including tags and logical data elements

Detailed Description Text (8):

Turning now to FIG. 1E, another communication link between the desktop computer C and the handheld computer H is shown. FIG. 1E shows the wireline technology--Internet combination to augment the wireless networks which may lack a ubiquitous infrastructure. FIG. 1E is similar to FIG. 1D, with the addition that an Internet link is interposed between the desktop computer C and the wireless carrier. In FIG. 1E, the wireless carrier communicates with an Internet service provider via a suitable protocol such as TCP/IP protocol. Originally developed as a reliable computer network for connecting research institutions and military sites, the Internet has become the world's most widely used computing network, where information is quickly and easily shared. Typically, data transmitted via the Internet via the World Wide Web still resembles that of the wireless packets, as the typical Web message size is small. Thus, in addition to wireless carriers, the handheld computer of the present invention can communicate with the desktop computer C via land lines, via wireless lines, or other means, including the Internet and variants thereof, including "intranets", or intra-corporation networks. These communication media meld computing power with network and wireless access, offering users significant leaps in productivity and accessibility.

Detailed Description Text (29):

In FIG. 6A, the synchronization software necessary to communicate synchronized data between the desktop computer C and the handheld computer H is shown in more detail. The synchronization software is the key to the desktop architecture as it contains the various components that together act to maintain data coherency. Turning now to FIG. 6A, the desktop computer C provides a coherency protocol engine 210, a communication engine 212, a data synchronization engine 214, tags 216, a signature table 218, a field map table 220, and a synchronization application programming interface (API) 222, which performs intermediate data transfer between the handheld computer H and the computer system C. Also, the desktop computer C has a plurality of applications, including the scheduler data engine 224, a phone list data engine 228, and a travel agent data engine 232, among others, as previously discussed. The communication port 212 communicates with the coherency protocol engine 210, which communicates with the data synchronization engine 214. The data synchronization engine 214 in turn communicates with tags 216 and the synchronization API 222. The tags 216 are coupled to the signature table 218 and the field mapping table 220. The synchronization API 222 is connected to data engines 224, 228 and 232 which communicate respectively with a scheduler personal information manager (PAM) 226, a phone list PIM 230 and a travel agent PIM 234, among other PIMs.

Current US Original Classification (1):709/248Current US Cross Reference Classification (4):709/246

CLAIMS:

15. A method for communicating data records between a handheld computer and a host computer, the handheld computer and host computer each having at least one common data set including logical data elements of a user database, each computer having copies of the common data set, the method comprising the steps of:

providing a pseudo cache having tag entries in the handheld computer corresponding to the logical data elements;

establishing a communication link between the handheld computer and the host computer in response to a change of a pseudo cache tag entry;

synchronizing data records stored by the handheld computer and the host computer, said synchronizing steps including:

searching tag entries of the pseudo cache for shared data records; and

modifying one or more of the tag entries coupled to said pseudo cache;

resolving any differences in the copies and storing identical copies of the common data set in the host computer and in the handheld computer.

[57] **ABSTRACT**

An apparatus is disclosed for performing dynamic synchronization between data stored in a handheld computer and a host computer, each having a plurality of data sets including at least one common data set, each computer having a copy of the common data set. The handheld computer has a processor, a communication port, and a data synchronization engine. The data synchronization engine has a pseudo-cache and one or more tags connected to the pseudo cache. Data is synchronized whenever data is written to main memory and/or when the associated pseudo-cache tag is invalidated. By strict adherence to a set of protocols, data coherency is achieved because the system always knows who owns the data, who has a copy of the data, and who has modified the data. The data synchronization engine resolves any differences in the copies and allows the storage of identical copies of the common data set in the host computer and in the handheld computer.

TITLE: Health management process control system

Detailed Description Text (10):

An even further advantage of using a compact video game system for handheld microprocessor 12 is that such video game systems include means for easily establishing the electrical interconnection provided by cable 14. In particular, such compact video game systems include a connector 40 mounted to the game unit housing and a cable that can be connected between the connectors of two video game units to allow interactive operation of the two interconnected units (i.e., to allow contemporaneous game play by two players or competition between players as they individually play identical but separate games). The cable supplied with handheld microprocessor unit 12 can be used as cable 14 to establish serial data communication between the handheld microprocessor unit 12 (compact video game system) and data management unit 10.

DOCUMENT-IDENTIFIER: US 6496874 B1

TITLE: Method and apparatus for determining position using a handheld personal computer and a cradle

Abstract Text (1):

A method and apparatus for determining position using a handheld personal computer. A cradle is disclosed that is adapted to couple to a handheld personal computer. In one embodiment, the cradle includes projecting members that capture the handheld personal computer and hold it securely in place. The cradle includes a position determining system that is adapted to determine position. Upon coupling the cradle to a handheld personal computer, the cradle is operable to determine position. Once position is determined, the determined position is displayed on the display of the handheld personal computer. The display can include a display of a moving map and an icon indicating the current position relative to the map. All required hardware and software for storing the map database and for determining position are included within the cradle.

DOCUMENT-IDENTIFIER: US 5666530 A

TITLE: System for automatic synchronization of common file between portable computer and host computer via communication channel selected from a plurality of usable channels there between

Abstract Text (1):

A handheld computer which contains an LCD display having a digitizing surface to allow pen input. Internal storage takes several forms, such as a large flash ROM area, battery-backed up RAM and an optional hard disk drive. Several alternative communication paths are available, such as the previously mentioned modem, a parallel printer port, a conventional serial port, a cradle assembly connected to the host computer, and various wireless short distance techniques such as radio frequency or infrared transmission. The computer can readily communicate with other sources, particularly to a host desktop computer, to allow automated synchronization of information between the host and the handheld system. Preferably the remote synchronization is performed at several user selectable levels. When the handheld computer is in a cradle and actively connected to the host computer, automatic capture of updated data in the host computer is performed. Several synchronization techniques are utilized to keep track of different types of files. In addition, while communication is established the handheld computer can enter a remote control mode, allowing the user access to files and applications not included in the handheld computer.

[57] ABSTRACT

A handheld computer which contains an LCD display having a digitizing surface to allow pen input. Internal storage takes several forms, such as a large flash ROM area, battery-backed up RAM and an optional hard disk drive. Several alternative communication paths are available, such as the previously mentioned modem, a parallel printer port, a conventional serial port, a cradle assembly connected to the host computer, and various wireless short distance techniques such as radio frequency or infrared transmission. The computer can readily communicate with other sources, particularly to a host desktop computer, to allow automated synchronization of information between the host and the handheld system. Preferably the remote synchronization is performed at several user selectable levels. When the handheld computer is in a cradle and actively connected to the host computer, automatic capture of updated data in the host computer is performed. Several synchronization techniques are utilized to keep track of different types of files. In addition, while communication is established the handheld computer can enter a remote control mode, allowing the user access to files and applications not included in the handheld computer.

TITLE: System for automatic synchronization of common file between portable computer and host computer via communication channel established with user approval of charge to be incurred

Abstract Text (1):

A handheld computer which contains an LCD display having a digitizing surface to allow pen input. Internal storage takes several forms, such as a large flash ROM area, battery-backed up RAM and an optional hard disk drive. Several alternative communication paths are available, such as the previously mentioned modem, a parallel printer port, a conventional serial port, a cradle assembly connected to the host computer, and various wireless short distance techniques such as radio frequency or infrared transmission. The computer can readily communicate with other sources, particularly to a host desktop computer, to allow automated synchronization of information between the host and the handheld system. Preferably the remote synchronization is performed at several user selectable levels. When the handheld computer is in a cradle and actively connected to the host computer, automatic capture of updated data in the host computer is performed. Several synchronization techniques are utilized to keep track of different types of files. In addition, while communication is established the handheld computer can enter a remote control mode, allowing the user access to files and applications not included in the handheld computer.

TITLE: System for automatic synchronization of common file between portable computer and host computer via communication channel established with user approval of charge to be incurred

Brief Summary Text (15):

Expense account program files are synchronized in a different fashion. When the handheld computer is in communication with the host computer, any time a new file or updated file is present in the handheld computer, it is automatically relayed back to the host computer to allow more permanent storage.
